It is well known that optimizing network topology by switching on and off transmission lines improves the efficiency of power delivery in electrical networks. In fact, the USA Energy Policy Act of 2005 (Section 1223) states that the United States should “encourage, as appropriate, the deployment of advanced transmission technologies” including “optimized transmission line configurations.” As such, many authors have studied the problem of determining an optimal set of transmission lines to switch off to minimize the cost of meeting a given power demand under the direct current (DC) model of power flow. This problem is known in the literature as the *Direct-Current Optimal Transmission Switching* Problem (DC-OTS). Most research on DC-OTS has focused on heuristic algorithms for generating quality solutions or on the application of DC-OTS to crucial operational and strategic problems such as contingency correction, real-time dispatch, and transmission expansion. The mathematical theory of the DC-OTS problem is less well developed. In this work, we formally establish that DC-OTS is NP-Hard, even if the power network is a series-parallel graph with at most one load/demand pair. Inspired by Kirchoff’s Voltage Law, we provide a cycle-based formulation for DC-OTS, and we use the new formulation to build a cycle-induced relaxation. We characterize the convex hull of the cycle-induced relaxation; this characterization provides strong valid inequalities that can be used in a cutting-plane approach to solve the DC-OTS. We give details of a practical implementation, and we show promising computational results on standard benchmark instances.

Keywords: integer programming; cutting plane/facets; electric industries.

Subject classifications: programming: integer: algorithms: cutting plane/facet; industries: electric.

Area of review: Optimization.

1. Introduction

An electric power grid is a complex engineered system whose control and operation is driven by fundamental laws of physics. The *optimal power flow* (OPF) problem is to determine a minimum cost delivery of a given demand for power subject to the power flow constraints implied by the network. The standard mathematical model of power flow uses alternating current (AC) power flow equations. The AC power flow equations are nonlinear and nonconvex, which has prompted the development of a linear approximation known as the direct current (DC) power flow equations. DC power flow equations are widely used in current industry

practice, and the DC OPF problem is a building block of power systems operations planning.

One consequence of the underlying physical laws of electric power flow is a type of “Braess’ Paradox” where removing lines from a transmission network may result in *improved* network efficiency. O’Neill et al. (2005) propose exploiting this well known attribute of power transmission networks by switching off lines to reduce generation costs. Fisher et al. (2008) formalized this notion into a mathematical optimization problem known as the Optimal Transmission Switching (OTS) problem. The OTS problem is the OPF problem augmented with the additional flexibility of changing

the network topology by removing transmission lines. While motivated in O'Neill et al. (2005) by an operational problem in which lines may be switched off to improve efficiency, the same mathematical switching structure also appears in longer term transmission network expansion planning problems.

Because of the mathematical complexity induced by the AC power flow equations, nearly all studies to date of the OTS problem have used the DC approximation to power flow (e.g., see Fisher et al. 2008, Barrows et al. 2012, Fuller et al. 2012, Wu and Cheung 2013). With this approximation, a mixed-integer linear programming (MILP) model for DC-OTS can be created and input to existing MILP software. In the MILP model, binary variables are used to model the changing topology and enforce the network power flow constraints on a line if and only if the line is present. Models with many “indicator constraints” of this form are often intractable for modern computational integer programming software, since the linear relaxations of the formulations are typically very weak. Previous authors have found this to be true for DC-OTS, and many heuristic methods have been developed based on ranking lines (Barrows et al. 2012, Fuller et al. 2012, Wu and Cheung 2013), or by imposing an (artificial) cardinality constraint on the number of lines that may be switched off in a solution (Fisher et al. 2008). The solutions obtained from these heuristics have demonstrated that significant efficiency gains are possible via transmission switching.

The paper by Coffrin et al. (2014) offers a criticism of the use of the DC-approximation to model power flow for the OTS problem. The paper demonstrates that a direct application of the DC power flow equations may *not* be accurate enough to recover useful AC operation solutions in the context of the OTS. They thus argue for the use of the AC-power flow equations in the OTS problem. The authors use a convex quadratic relaxation of the AC power flow equations proposed in Hijazi et al. (2013) and embed the relaxation in a branch-and-bound method to solve the AC-OTS problem. Recent papers by Barrows et al. (2014) and Soroush and Fuller (2014) also develop methods and heuristics for AC-OTS.

Despite the criticism of the DC power flow model for optimal transmission switching, there are many planning problems for which the DC power flow model may be an acceptable approximation when combined with network topology changes. A survey in Hedman et al. (2011) enumerates applications of transmission switching to improve voltage profiles, reduce congestion and losses in the system, and increase power grid reliability. A standard reliability criterion for the power grid is that the system must be able to withstand an “ $N - 1$ ” event. In an interconnection network with N elements, the system will operate reliably following the failure of any one of them. Hedman et al. (2009) augment the DC-OTS model to ensure that the $N - 1$ reliability criteria is satisfied. Heuristics are used to iteratively decide which lines are to be switched off, while preserving $N - 1$ reliability for standard test cases. The authors show that

significant cost savings from transmission switching is still possible even if the $N - 1$ contingency is required.

Transmission switching is also an important subproblem in power grid capacity expansion planning. In Khodaei et al. (2010), a large MILP model is constructed to solve an expansion planning problem with contingencies, the DC power flow equations are used, and transmission switching is allowed to find the best configuration. Villumsen and Philpott (2012) develop a slightly different model for expansion planning that also relies on the DC-power flow approximation and transmission switching. They use their method on a case study for a real power system expansion plan in Denmark (see Villumsen et al. 2013). In the context of expansion planning, note that the mathematical structure of line addition is exactly the same as line removal.

Authors who have combined the DC-approximation to power flow with the flexibility of modifying the network topology have found that the resulting MILP programming model is very challenging and called for a more systematic study on its underlying mathematical structure. For example, Hedman et al. (2010, p. 1058) state that

“When solving the transmission switching problem, ... the techniques for closing the optimality gap, specifically improving the lower bound, are largely ineffective.”

A primary focus of our work is an attempt to change this reality by developing strong classes of valid inequalities that may be applied to power systems planning problems that involve the addition or removal of transmission elements. Our paper makes the following contributions:

- Using a formulation based on Kirchoff’s Voltage Law, we give a cycle-based linear mixed integer programming (MIP) formulation for DC-OTS.
- We formally establish that the DC-OTS problem is NP-Hard, even if the interconnection network is a series-parallel graph and there is only one generation/demand pair. (Additional complexity results were recently independently established by Lehmann et al. 2014).
- Using the cycle-based formulation as inspiration, we derive classes of strong valid inequalities for a cycle-relaxation of the DC-OTS. We also establish that inequalities define the convex hull of the cycle-relaxation, and we show how to separate the inequalities over a given cycle in polynomial time.
- We perform computational experiments focusing on improving performance of integer programming-based methods for the OTS using the DC power flow approximation. We show that the new inequalities can help improve solution performance of commercial MIP software.

Although our valid inequalities are new, they expand the body of literature that has made productive use of cycles in a graph to derive valid inequalities for discrete optimization problems, see e.g., Padberg (1973), Barahona and Mahjoub (1986), Ferreira et al. (1996), Van Vyve (2005) for a few examples.

2. DC OPF and OTS Formulations

A power network consists of a set of buses \mathcal{B} , transmission lines \mathcal{L} , and generators $\mathcal{G} \subseteq \mathcal{B}$. We assume that the graph $G = (\mathcal{B}, \mathcal{L})$ is connected. Each line $(i, j) \in \mathcal{L}$ is given an (arbitrary) orientation, with the convention that power flow in the direction from $i \rightarrow j$ is positive, while power that flows along line (i, j) in the direction $j \rightarrow i$ is negative. Each bus $i \in \mathcal{B}$ has a set of adjacent buses $\delta(i) \subseteq \mathcal{B}$. We use the standard notation that $\delta^+(i) := \{j \in \mathcal{B}: (i, j) \in \mathcal{L}\}$ and $\delta^-(i) := \{j \in \mathcal{B}: (j, i) \in \mathcal{L}\}$. The required load at each bus is given as p_i^d , $i \in \mathcal{B}$. In the DC model, power flow on a transmission line is proportional to the difference in phase angles of voltages at the two ends of the line. The constant of proportionality is known as the *susceptance* of line $(i, j) \in \mathcal{L}$, which we denote as B_{ij} . Each transmission line $(i, j) \in \mathcal{L}$ has an upper bound \bar{f}_{ij} on the allowed power flow. Finally, the power produced at each generator $i \in \mathcal{G}$ is constrained to lie in the interval $[p_i^{\min}, p_i^{\max}]$ with an associated unit production cost of c_i . We assume that there is at most one generator at each bus. This assumption is without loss of generality (wlog), since the models we present can be extended to the case with multiple generators by replacing the dispatch variable by the sum of different dispatch variables attached to a particular bus. We also assume that the cost is a linear function of the production quantities at the generators. This assumption, while standard in the literature surrounding the DC-OTS (Fisher et al. 2008, Fuller et al. 2012), ignores the convex quadratic portion of generation costs. As discussed in §4, our formulation and valid inequalities can still be applied when the cost is a nonlinear function.

2.1. Angle Formulation of DC-OPF

The standard formulation of DC OPF has three classes of decision variables. The variable p_i^g is the power generation at generator $i \in \mathcal{G}$, and the variable θ_i is the voltage angle at bus $i \in \mathcal{B}$. The variable f_{ij} represents the power flow along line $(i, j) \in \mathcal{L}$. With these decision variables, we can write a linear programming problem to minimize the generation cost of meeting power demands p_i^d as follows:

$$\min \sum_{i \in \mathcal{G}} c_i p_i^g \quad (1a)$$

$$\text{s.t. } p_i^g - p_i^d = \sum_{j \in \delta^+(i)} f_{ij} - \sum_{j \in \delta^-(i)} f_{ji} \quad i \in \mathcal{B} \quad (1b)$$

$$B_{ij}(\theta_i - \theta_j) = f_{ij} \quad (i, j) \in \mathcal{L} \quad (1c)$$

$$-\bar{f}_{ij} \leq f_{ij} \leq \bar{f}_{ij} \quad (i, j) \in \mathcal{L} \quad (1d)$$

$$p_i^{\min} \leq p_i^g \leq p_i^{\max} \quad i \in \mathcal{G}. \quad (1e)$$

By substituting the definition of power flow from (1c) in Equations (1b) and (1d), the f variables may be projected out of the formulation.

2.2. Cycle Formulation of DC-OPF

The DC power flow model gets its name from the fact that the equations describing the power flow in network are the same as those that describe current flow in a standard direct current electric network. The constraints (1b) describe Kirchoff's Current Law (KCL) at each bus, and the Equations (1c) that define the branch current follow from Ohm's Law. With this analogy, it is natural to think about the alternative way to represent power flows in a DC circuit, using the branch current f_{ij} and Kirchoff's Voltage Law (KVL). KVL states that around any *directed* cycle C , the voltage differences must sum to zero:

$$\sum_{(i,j) \in C} (\theta_i - \theta_j) = \sum_{(i,j) \in C} \frac{f_{ij}}{B_{ij}} = 0. \quad (2)$$

If the directed cycle C contains arc (i, j) , but the transmission line has been given the alternate orientation $((j, i) \in \mathcal{L})$, we adjust (2) by flipping the sign of the susceptance:

$$\bar{B}_{ij}^C = \begin{cases} B_{ij} & \text{if } (i, j) \in C, (i, j) \in \mathcal{L} \\ -B_{ij} & \text{if } (i, j) \in C, (j, i) \in \mathcal{L}. \end{cases}$$

Our formulation of the DC-OPF relies on the notion of a *cycle basis*.

DEFINITION 2.1 (HARIHARAN ET AL. 2008). Let $v \in \{0, \pm 1\}^{|\mathcal{L}|}$ be an incidence vector for a cycle C in graph $G = (\mathcal{B}, \mathcal{L})$, where

$$v_{ij} = \begin{cases} 1 & \text{if } (i, j) \text{ is traversed in the right} \\ & \text{direction by } C \\ -1 & \text{if } (i, j) \text{ is traversed in the opposite} \\ & \text{direction by } C \\ 0 & \text{if } (i, j) \text{ is not in } C. \end{cases}$$

The *cycle space* of G is the vector space spanned by the incidence vectors of its cycles. A set of cycles is called a *cycle basis* if it forms a basis for this vector space.

A cycle basis of G is then a minimal set of cycles of G with the property that all cycles of G are linear combinations of the cycles in the basis.

In this equivalent representation, the power flow should satisfy the KVL (2) for each cycle. Although the number of cycles in a network can be large, it is sufficient to enforce (2) over any set of cycles that forms a cycle basis \mathcal{C}_b of the network. If angle differences sum up to zero over the cycle basis, they also must sum up to zero over any other cycle (e.g., see Bollobás 2002). Thus, the KVL-inspired formulation for the DC OPF is the following:

$$\min \sum_{i \in \mathcal{G}} c_i p_i^g \quad (3a)$$

$$\text{s.t. } (1b), (1d), (1e) \quad (3b)$$

$$\sum_{(i,j) \in C} \frac{f_{ij}}{\bar{B}_{ij}^C} = 0 \quad C \in \mathcal{C}_b. \quad (3c)$$

The voltage angles may be recovered using the Equations (1c).

PROPOSITION 2.1. *Formulations (1) and (3) are equivalent.*

PROOF. To prove the equivalence of the formulations, it suffices to show that

$$\sum_{(i,j) \in C} \frac{f_{ij}}{\bar{B}_{ij}^C} = 0, \quad C \in \mathcal{C}_b$$

$$\iff \exists \theta, \quad f_{ij} = B_{ij}(\theta_i - \theta_j), \quad (i, j) \in \mathcal{L}. \quad (4)$$

(\Rightarrow) First observe that because \mathcal{C}_b is a cycle basis, Equations (3c) imply $\sum_{(i,j) \in C} (f_{ij}/\bar{B}_{ij}^C) = 0$ for any cycle C . Now let $\mathcal{T} = (\mathcal{B}, \mathcal{L}')$ be a spanning tree of G . Clearly, the following system in θ has a solution:

$$B_{ij}(\theta_i - \theta_j) = f_{ij}, \quad (i, j) \in \mathcal{L}'. \quad (5)$$

Therefore, it suffices to check if a solution of (5) satisfies $B_{ij}(\theta_i - \theta_j) = f_{ij}$ for $(i, j) \in \mathcal{L} \setminus \mathcal{L}'$. Note that for any $(k, l) \in \mathcal{L} \setminus \mathcal{L}'$, there exists a unique path \mathcal{P}_{kl} from k to l in \mathcal{T} and a cycle $C = \mathcal{P}_{kl} \cup \{(l, k)\}$. Then, we have

$$(\theta_k - \theta_l) = \sum_{(i,j) \in \mathcal{P}_{kl}} (\theta_i - \theta_j) = \sum_{(i,j) \in \mathcal{P}_{kl}} \frac{f_{ij}}{\bar{B}_{ij}^C} = \frac{f_{kl}}{\bar{B}_{kl}^C}, \quad (6)$$

which implies $B_{kl}(\theta_k - \theta_l) = f_{kl}$.

(\Leftarrow) Suppose there exist θ such that $f_{ij} = B_{ij}(\theta_i - \theta_j)$, for each $(i, j) \in \mathcal{L}$. Then, for each cycle C , we have

$$\sum_{(i,j) \in C} \frac{f_{ij}}{\bar{B}_{ij}^C} = \sum_{(i,j) \in C} \frac{B_{ij}(\theta_i - \theta_j)}{\bar{B}_{ij}^C} = \sum_{(i,j) \in C} (\theta_i - \theta_j) = 0, \quad (7)$$

which concludes the proof. \square

2.3. Angle Formulation of DC-OTS

The angle-based DC-OPF formulation (1) can be easily adapted to switching by introducing binary variables x_{ij} that take the value 1 if line $(i, j) \in \mathcal{L}$ is on, and 0 if the line is disconnected. A direct nonlinear formulation of DC-OTS is

$$\min \sum_{i \in \mathcal{N}} c_i p_i^g \quad (8a)$$

$$\text{s.t. (1b), (1d), (1e)} \quad (8b)$$

$$B_{ij}(\theta_i - \theta_j)x_{ij} = f_{ij} \quad (i, j) \in \mathcal{L} \quad (8c)$$

$$x_{ij} \in \{0, 1\} \quad (i, j) \in \mathcal{L}. \quad (8d)$$

The constraints (8c) ensure that Ohm's Law (1c) is enforced if the line is switched on and that power flow $f_{ij} = 0$ if the line is switched off. However, these constraints (8c) contain nonlinear, nonconvex terms of the form $\theta_i x_{ij}$. The standard way to linearize the inequalities (8c) is used by Fisher et al. (2008) to produce the following formulation:

$$\min \sum_{i \in \mathcal{N}} c_i p_i^g \quad (9a)$$

$$\text{s.t. (1b), (1e), (8d)} \quad (9b)$$

$$B_{ij}(\theta_i - \theta_j) - M_{ij}(1 - x_{ij}) \leq f_{ij}$$

$$\leq B_{ij}(\theta_i - \theta_j) + M_{ij}(1 - x_{ij}) \quad (i, j) \in \mathcal{L} \quad (9c)$$

$$-\bar{f}_{ij}x_{ij} \leq f_{ij} \leq \bar{f}_{ij}x_{ij} \quad (i, j) \in \mathcal{L}, \quad (9d)$$

where M_{ij} is chosen sufficiently large to make the inequalities (9c) redundant if $x_{ij} = 0$.

2.4. Cycle Formulation of DC-OTS

Inspired by the cycle formulation (3) for the DC-OPF, we can formulate the DC-OTS problem without angle variables as well. The full formulation enforces KVL only if all arcs in a cycle are switched on.

$$\min \sum_{i \in \mathcal{N}} c_i p_i^g \quad (10a)$$

$$\text{s.t. (1b), (1e), (8d), (9d)} \quad (10b)$$

$$-M_C \sum_{(i,j) \in C} (1 - x_{ij}) \leq \sum_{(i,j) \in C} \frac{f_{ij}}{\bar{B}_{ij}^C}$$

$$\leq M_C \sum_{(i,j) \in C} (1 - x_{ij}) \quad C \in \mathcal{C}. \quad (10c)$$

The value M_C must be selected so that the inequalities (10c) are redundant if $\sum_{(i,j) \in C} (1 - x_{ij}) \geq 1$. In formulation (10), \mathcal{C} is the set of all cycles in the graph $G = (\mathcal{B}, \mathcal{L})$. Because the cardinality of \mathcal{C} is, in general, quite large, we do not propose using (10) directly. Rather, we use the formulation (10) as the starting point for deriving strong valid inequalities in §4. Furthermore, the inequalities (10c) could be added as cuts within a branch-and-cut algorithm. These inequalities are required to define the feasible region; the branch-and-cut procedure would search for a violated inequality from the class (10c) any time it identifies a candidate solution with the x components binary. (Inequalities added as cuts in this way are sometimes called “lazy cuts.”)

3. Complexity of DC-OTS

In this section, we discuss the complexity of the DC-OTS problem. The input to the problem is a power network as described at the beginning of §2. In the *feasibility version* of DC-OTS, we ask if there *exists* a subset of lines to switch off such that the DC-OPF is feasible for the induced topology. The feasibility version of DC-OTS with a cardinality constraint has been proven to be NP-Complete in Bienstock and Mattia (2007) by reduction from the Exact 3-Cover Problem. Recently, many complexity and approximability results on DC-Switching problems were given in Lehmann et al. (2014), including the result that DC-OTS is NP-Hard, even if the underlying graph is a cactus. Our results were established independently, and complement the results of Lehmann et al. (2014) by formally establishing that the DC-OTS problem is easy if the graph is a tree and NP-Hard even if there is one generation/load pair on series-parallel graphs.

PROPOSITION 3.1. *In the DC-OTS, there exists an optimal solution in which the lines switched on form a connected network.*

PROOF. Consider the Cycle Formulation (10) of the DC-OTS. Let \mathcal{L}' be the active lines in an optimal solution. Assume that the network corresponding to this solution has k connected components. Because the original network

$G(\mathcal{B}, \mathcal{L})$ is connected, we can find a set of transmission lines \mathcal{L}'' with cardinality $k - 1$ such that $G' = (\mathcal{B}, \mathcal{L}' \cup \mathcal{L}'')$ is connected. Now, let $x_{ij} = 1$ and $f_{ij} = 0$ for all $(i, j) \in \mathcal{L}''$. By construction, no new cycles are created by switching on lines in \mathcal{L}'' . Furthermore, the balance constraints (1b) and bound constraints (9d) are satisfied. Hence, we have demonstrated a new solution with the same objective value where the network formed by the active lines is connected. \square

COROLLARY 3.1. *If $G = (\mathcal{B}, \mathcal{L})$ is a tree, the DC-OTS problem is solvable in polynomial time.*

PROOF. Due to Proposition 3.1, there exists an optimal solution that induces a connected network. Since removing any line disconnects the tree, there exists an optimal solution in which all lines are active. Yet this is exactly the DC-OPF problem without switching, which can be solved via linear programming, a problem known to be polynomially solvable. \square

Theorem 3.1 establishes that DC-OTS is NP-Complete even if the power network is a series-parallel graph, and there is only one demand-supply pair.

THEOREM 3.1. *The feasibility version of DC-OTS is NP-complete even when $G = (\mathcal{B}, \mathcal{L})$ is a series-parallel graph, there is $|\mathcal{G}| = 1$ generator, and one node $i \in \mathcal{B}$ such that $p_i^d \neq 0$.*

PROOF. We prove this result by a reduction from the subset sum problem, which is known to be NP-Complete (Garey and Johnson 1979). Consider an instance of a subset problem as: Given $a_i \in \mathbb{Z}_{++}$ for $i \in \{1, \dots, n\}$ and $b \in \mathbb{Z}_{++}$, does there exist a subset $I \subseteq \{1, \dots, n\}$ such that $\sum_{i \in I} a_i = b$? We construct an instance of a switching problem as follows:

1. There are $n + 3$ buses $\{0, 1, \dots, n, n + 1, n + 2\}$.
2. Following are the lines: $(0, i)$ for all $i \in \{1, \dots, n\}$; $(i, n + 1)$ for all $i \in \{1, \dots, n\}$; $(n + 1, n + 2)$; $(0, n + 2)$.
3. The capacities of the lines are: a_i/b for the line $(0, i)$ and $(i, n + 1)$ for all $i \in \{1, \dots, n\}$; 1 for $(n + 1, n + 2)$ and $(0, n + 2)$.
4. The susceptances of the lines are: $2a_i$ for the line $(0, i)$ and $(i, n + 1)$ for all $i \in \{1, \dots, n\}$; 1 for $(n + 1, n + 2)$; $b/(b + 1)$ for $(0, n + 2)$.
5. There is a generation of 2 at bus 0 and load of 2 at bus $n + 2$.

Clearly, the size of the instance of the switching problem is polynomial in the size of the given instance of the subset sum problem. Note also that the graph is a series-parallel graph and there is only one demand supply pair.

We now verify that the subset sum problem is feasible if and only if the switching problem is feasible.

(\Rightarrow): Since the subset sum problem is feasible, let $\sum_{i \in I} a_i = b$ where $I \subseteq \{1, \dots, n\}$. Then construct a solution to the switching problem as follows: Switch off the lines $(0, i)$, $(i, n + 1)$ for $i \in \{1, \dots, n\} \setminus I$. It is straightforward to establish that a feasible solution to the DC-OTS exists. (In the solution, the angle at bus 0 is $1 + 1/b$, the angle at bus i

is $1 + 1/(2b)$ for all $i \in I$, the angle at bus $n + 1$ is 1, and the angle at bus $n + 2$ is 0).

(\Leftarrow): The subset sum problem is infeasible; assume by contradiction that the switching problem is feasible. Then note that the flow in arcs $(0, n + 2)$ and $(n + 1, n + 2)$ is 1 each (and these lines are not switched off). Wlog, let the angle at bus $n + 2$ be 0. This implies that the angle at bus 0 is $1 + 1/b$ and at bus $n + 1$ is 1. Then note that if a pair of lines $(0, i)$, $(i, n + 1)$ is not switched off, this implies that the angle at bus i is $1 + 1/(2b)$ and the resulting flow is a_i/b along the path $(0, i)$, $(i, n + 1)$. Therefore, as a switching solution exists, we have that there exists some $I \subseteq \{1, \dots, n\}$ such that the paths $(0, i)$, $(i, n + 1)$ for $i \in I$ are switched on (and others are switched off). Then $\sum_{i \in I} (a_i/b) = 1$ (by flow conservation at bus $n + 1$), the required contradiction. \square

4. Valid Inequalities

In this section, we give two (symmetric) classes of inequalities for DC-OTS that are derived by considering a relaxation of the cycle formulation (10). The inequalities are derived by projecting an extended formulation of our chosen relaxation. We additionally show that the inequalities define the convex hull of the relaxation and that each of the inequalities defines a facet of the relaxation. The separation problem for the new class of inequalities is a knapsack problem, but we show in §4.2 how to exploit the special structure of the knapsack to give a closed-form solution.

Remember that the objective function is assumed to be linear, as opposed to convex quadratic. In general, finding the convex hull of the feasible region may not be as algorithmically useful when the objective function is nonlinear convex as the optimal solution may lie in the interior of the convex hull. However, the generation cost functions are usually convex increasing functions of p_i^g over the interval $[p_i^{\min}, p_i^{\max}]$. Therefore, the optimal solutions of any convex relaxation will lie on the boundary of the relaxation. Thus, finding the convex hull of the feasible solutions may still be useful in improving bounds when we are working with a convex quadratic increasing objective function instead of a linear objective function. Nevertheless, note also that when the optimal solution is not an extreme point, the bound obtained by this approach might be weak. As a future work, numerical experiments should be carried out to analyze this case empirically.

4.1. Derivation

Consider the constraints (10c), (9d) and (8d) in the cycle-based formulation for DC-OTS for one specific cycle $C \in \mathcal{C}$ and define the following relaxation of the feasible region of (10).

$$\mathcal{S}_C = \left\{ (f, x) : -M_C \sum_{(i,j) \in C} (1 - x_{ij}) \leq \sum_{(i,j) \in C} \frac{f_{ij}}{\bar{B}_{ij}^C} \right. \\ \left. \leq M_C \sum_{(i,j) \in C} (1 - x_{ij}), -\bar{f}_{ij} x_{ij} \leq f_{ij} \leq \bar{f}_{ij} x_{ij} \right.$$

$$(i, j) \in C, x_{ij} \in \{0, 1\} \ (i, j) \in C \}. \quad (11)$$

In the remainder of this section, we assume that C is a directed cycle and hence, $\bar{B}_{ij}^C = B_{ij}$. Our main result in this section concerns the inequalities

$$\begin{aligned} & -\Delta(S)(|C| - 1) + \sum_{(i,j) \in S} [\Delta(S) - w_{ij}]x_{ij} + \Delta(S) \sum_{(i,j) \in C \setminus S} x_{ij} \\ & \leq \sum_{(i,j) \in S} \frac{f_{ij}}{B_{ij}} \leq \Delta(S)(|C| - 1) - \sum_{(i,j) \in S} [\Delta(S) - w_{ij}]x_{ij} \\ & \quad - \Delta(S) \sum_{(i,j) \in C \setminus S} x_{ij} \\ & S \subseteq C \quad \text{s.t. } \Delta(S) > 0, \end{aligned} \quad (12)$$

where $w_{ij} := \bar{f}_{ij}/B_{ij}$, and

$$w(S) := \sum_{(i,j) \in S} w_{ij} \quad \text{for } S \subseteq C$$

$$\Delta(S) := w(S) - w(C \setminus S) = 2w(S) - w(C) \quad \text{for } S \subseteq C.$$

We show that the inequalities (12) are the only nontrivial inequalities defining $\text{conv}(\mathcal{P}_C)$.

THEOREM 4.1.

$$\begin{aligned} \text{conv}(\mathcal{P}_C) = \{(f, x) : & \text{(12)}, -\bar{f}_{ij}x_{ij} \leq f_{ij} \\ & \leq \bar{f}_{ij}x_{ij}, x_{ij} \leq 1 \ (i, j) \in C\} \end{aligned} \quad (13)$$

In proving this result, for ease of presentation, we assume WLOG that $B_{ij} = 1$ for all $(i, j) \in \mathcal{L}$ by appropriately scaling \bar{f}_{ij} . The result is proven through a series of propositions using disjunctive arguments. We start with the following linear system:

$$-\bar{f}_{ij}x_{ij}^1 \leq f_{ij}^1 \leq \bar{f}_{ij}x_{ij}^1 \quad (i, j) \in C \quad (14a)$$

$$\sum_{(i,j) \in C} x_{ij}^1 = |C|y_C \quad (14b)$$

$$\sum_{(i,j) \in C} f_{ij}^1 = 0 \quad (14c)$$

$$0 \leq x_{ij}^1 \leq y_C \quad (i, j) \in C \quad (14d)$$

$$-\bar{f}_{ij}x_{ij}^0 \leq f_{ij}^0 \leq \bar{f}_{ij}x_{ij}^0 \quad (i, j) \in C \quad (14e)$$

$$\sum_{(i,j) \in C} x_{ij}^0 \leq (|C| - 1)(1 - y_C) \quad (14f)$$

$$0 \leq x_{ij}^0 \leq 1 - y_C \quad (i, j) \in C \quad (14g)$$

$$x_{ij} = x_{ij}^1 + x_{ij}^0 \quad (i, j) \in C \quad (14h)$$

$$f_{ij} = f_{ij}^1 + f_{ij}^0 \quad (i, j) \in C \quad (14i)$$

$$0 \leq y_C \leq 1, \quad (14j)$$

and define the polytope

$$\mathcal{E}_C = \{(f, f^1, f^0, x, x^1, x^0, y) : \text{(14)}\}.$$

PROPOSITION 4.1. System (14) is an extended formulation for $\text{conv}(\mathcal{P}_C)$. Furthermore, polytope \mathcal{E}_C is integral so that we have $\text{conv}(\mathcal{P}_C) = \text{proj}_{f,x} \mathcal{E}_C$.

PROOF. We first consider the following disjunction for cycle C : Either every line is active or at least one line is disconnected. If all the lines are active, then we have

$$-\bar{f}_{ij}x_{ij} \leq f_{ij} \leq \bar{f}_{ij}x_{ij} \quad (i, j) \in C \quad (15a)$$

$$\sum_{(i,j) \in C} x_{ij} = |C| \quad (15b)$$

$$\sum_{(i,j) \in C} f_{ij} = 0 \quad (15c)$$

$$0 \leq x_{ij} \leq 1 \quad (i, j) \in C \quad (15d)$$

Define polytope $\mathcal{P}_C^1 = \{(f, x) : \text{(15)}\}$. Note that \mathcal{P}_C^1 is integral in x since constraint (15b) forces $x_{ij} = 1$ for all $(i, j) \in C$ in a feasible solution.

Otherwise, at least one of the lines is inactive and we have

$$-\bar{f}_{ij}x_{ij} \leq f_{ij} \leq \bar{f}_{ij}x_{ij} \quad (i, j) \in C \quad (16a)$$

$$\sum_{(i,j) \in C} x_{ij} \leq |C| - 1 \quad (16b)$$

$$0 \leq x_{ij} \leq 1 \quad (i, j) \in C \quad (16c)$$

Define polytope $\mathcal{P}_C^0 = \{(f, x) : \text{(16)}\}$, which is again integral in x .

By construction, we have $\text{conv}(\mathcal{P}_C) = \text{conv}(\mathcal{P}_C^1 \cup \mathcal{P}_C^0)$. We duplicate variables (f, x) as (f^1, x^1) and (f^0, x^0) in the descriptions of \mathcal{P}_C^1 and \mathcal{P}_C^0 , respectively. Then, by assigning a binary variable y_C to \mathcal{P}_C^1 and $1 - y_C$ to \mathcal{P}_C^0 , we get system (14). So, it is an extended formulation for $\text{conv}(\mathcal{P}_C)$.

Furthermore, observe that \mathcal{E}_C is the union of two polyhedra that are integral in x : $\mathcal{E}_C = \mathcal{P}_C^1 \cup \mathcal{P}_C^0$. Therefore, \mathcal{E}_C must be integral in x as well. \square

By noting that $x_{ij}^1 = y_C$ and $x_{ij}^0 = x_{ij} - y_C$, we can simplify the notation by immediately projecting out these variables. Specifically, if we define the linear system

$$-\bar{f}_{ij}y_C \leq f_{ij}^1 \leq \bar{f}_{ij}y_C \quad (i, j) \in C \quad (17a)$$

$$\sum_{(i,j) \in C} f_{ij}^1 = 0 \quad (17b)$$

$$-\bar{f}_{ij}(x_{ij} - y_C) \leq f_{ij}^0 \leq \bar{f}_{ij}(x_{ij} - y_C) \quad (i, j) \in C \quad (17c)$$

$$\sum_{(i,j) \in C} x_{ij} - y_C \leq |C| - 1 \quad (17d)$$

$$y_C \leq x_{ij} \leq 1 \quad (i, j) \in C \quad (17e)$$

$$f_{ij} = f_{ij}^1 + f_{ij}^0 \quad (i, j) \in C \quad (17f)$$

$$0 \leq y_C \leq 1, \quad (17g)$$

we have that

$$\mathcal{P}_C := \{(f, f^1, f^0, x, y) : \text{(17)}\} = \text{proj}_{f, f^1, f^0, x, y} \mathcal{E}_C.$$

In Proposition 4.2 we can further project the f^1 and f^0 variables by defining

$$\begin{aligned}
 - \sum_{(i,j) \in S} w_{ij}x_{ij} + \Delta(S)y_C &\leq \sum_{(i,j) \in S} f_{ij} \\
 &\leq \sum_{(i,j) \in S} w_{ij}x_{ij} - \Delta(S)y_C \\
 S \subseteq C \quad \text{s.t. } \Delta(S) > 0. & \tag{18}
 \end{aligned}$$

PROPOSITION 4.2. $\text{proj}_{f,x,y} \mathcal{P}_C = \{(f, x, y): (9d), (18), (17d), (17e), y_C \geq 0\}$.

PROOF. First, we define $\mathcal{Q} := \{(f, x, y): (9d), (18), (17d), (17e), y_C \geq 0\}$, and let $(f, f^1, f^0, x, y) \in \mathcal{P}_C$. We claim that $(f, x, y) \in \mathcal{Q}$. For each line $(i, j) \in C$, summing (17a) and (17c) and using (17f) yields (9d). So, it suffices to check constraint (18). We have, for each $S \subseteq C$,

$$0 = \sum_{(i,j) \in C} f_{ij}^1 = \sum_{(i,j) \in S} f_{ij}^1 + \sum_{(i,j) \in C \setminus S} f_{ij}^1$$

due to (17b). Recall that by scaling \bar{f}_{ij} , we have assumed $B_{ij} = 1$, and thus $w_{ij} = \bar{f}_{ij}$ for all $(i, j) \in \mathcal{L}$. Combined with (17f), we have

$$\begin{aligned}
 \sum_{(i,j) \in S} f_{ij} &= \sum_{(i,j) \in S} f_{ij}^0 - \sum_{(i,j) \in C \setminus S} f_{ij}^1 \\
 &\leq \sum_{(i,j) \in S} \bar{f}_{ij}(x_{ij} - y_C) + \sum_{(i,j) \in C \setminus S} \bar{f}_{ij}y_C \\
 &\quad \text{due to (17c) and (17a)} \\
 &= \sum_{(i,j) \in S} w_{ij}x_{ij} - \left(\sum_{(i,j) \in S} w_{ij} - \sum_{(i,j) \in C \setminus S} w_{ij} \right) y_C \\
 &= \sum_{(i,j) \in S} w_{ij}x_{ij} - \Delta(S)y_C. \tag{19}
 \end{aligned}$$

This is exactly the right inequality of (18). Note that although this inequality is valid for all $S \subseteq C$, the ones with $\Delta(S) \leq 0$ are dominated. In fact, due to (9d) for a subset \bar{S} with $\Delta(\bar{S}) \leq 0$, we have

$$\sum_{(i,j) \in \bar{S}} f_{ij} \leq \sum_{(i,j) \in \bar{S}} w_{ij}x_{ij} \leq \sum_{(i,j) \in \bar{S}} w_{ij}x_{ij} - \Delta(\bar{S})y_C. \tag{20}$$

Using a symmetric argument, we can similarly show the validity of the left inequality. Hence, $\text{proj}_{f,x,y} \mathcal{P}_C \subseteq \mathcal{Q}$.

Next, we prove that any solution $(f, x, y) \in \mathcal{Q}$ can be extended by some (f^1, f^0) such that it satisfies (17). First, we can eliminate f^0 variables by setting $f_{ij}^0 = f_{ij} - f_{ij}^1$. Therefore to show that $\text{proj}_{f,x,y} \mathcal{P}_C \supseteq \mathcal{Q}$, it suffices to show that, for any $(f, x, y) \in \mathcal{Q}$, the following system in f_{ij}^1 is always feasible:

$$-w_{ij}y_C \leq f_{ij}^1 \leq w_{ij}y_C \quad (i, j) \in C \tag{21a}$$

$$f_{ij} - w_{ij}(x_{ij} - y_C) \leq f_{ij}^1 \leq f_{ij} + w_{ij}(x_{ij} - y_C) \quad (i, j) \in C \tag{21b}$$

$$\sum_{(i,j) \in C} f_{ij}^1 = 0, \tag{21c}$$

which is the intersection of a hypercube defined by (21a)–(21b) and a hyperplane (21c). First note that the hypercube is always nonempty due to (9d). Then, due to the continuity of the function $\sum_{(i,j) \in C} f_{ij}^1$, it suffices to show the following inequalities:

$$\begin{aligned}
 \min \left\{ \sum_{(i,j) \in C} f_{ij}^1: (21a), (21b) \right\} &\leq 0 \\
 &\leq \max \left\{ \sum_{(i,j) \in C} f_{ij}^1: (21a), (21b) \right\}. \tag{22}
 \end{aligned}$$

We show that (22) follows from (18). To see this, let us examine the right inequality in (22). The left one can be obtained symmetrically. Since (21a)–(21b) define a hypercube, the maximum in (22) is obtained by maximizing each f_{ij}^1 over its own interval, i.e., we have

$$\begin{aligned}
 \max \left\{ \sum_{(i,j) \in C} f_{ij}^1: (21a), (21b) \right\} \\
 &= \sum_{(i,j) \in C} \min \left\{ w_{ij}y_C, f_{ij} + w_{ij}(x_{ij} - y_C) \right\} \\
 &= \sum_{(i,j) \in S} f_{ij} + w_{ij}(x_{ij} - y_C) + \sum_{(i,j) \in C \setminus S} w_{ij}y_C \\
 &= \sum_{(i,j) \in S} f_{ij} + w_{ij}x_{ij} - \Delta(S)y_C \geq 0, \tag{23}
 \end{aligned}$$

where $S = \{(i, j) \in C: f_{ij} + w_{ij}(x_{ij} - y_C) \leq w_{ij}y_C\}$ and (23) is exactly the left-hand side (LHS) inequality in (18). \square

We complete the proof of Theorem 4.1 by projecting the y_C variable as well.

PROOF. (Proof of Theorem 4.1.) By construction, we have that $\text{conv}(\mathcal{S}_C) = \text{proj}_{f,x} \mathcal{P}_C$. It suffices to show that $\text{conv}(\mathcal{S}_C) = \text{proj}_{f,x} \mathcal{P}_C = \mathcal{R}$ where $\mathcal{R} = \{(f, x): (9d), (12), x_{ij} \leq 1 (i, j) \in C\}$.

First, we rewrite inequalities involving y_C in $\text{proj}_{f,x,y} \mathcal{P}_C$:

$$0 \leq y_C \tag{24a}$$

$$\sum_{(i,j) \in C} x_{ij} - (|C| - 1) \leq y_C \tag{24b}$$

$$y_C \leq x_{ij} \quad (i, j) \in C \tag{24c}$$

$$y_C \leq \frac{1}{\Delta(S)} \sum_{(i,j) \in S} w_{ij}x_{ij} + \frac{1}{\Delta(S)} \sum_{(i,j) \in S} f_{ij} \quad S \subseteq C, \Delta(S) > 0 \tag{24d}$$

$$y_C \leq \frac{1}{\Delta(S)} \sum_{(i,j) \in S} w_{ij}x_{ij} - \frac{1}{\Delta(S)} \sum_{(i,j) \in S} f_{ij} \quad S \subseteq C, \Delta(S) > 0. \tag{24e}$$

Now, we use Fourier-Motzkin elimination on y_C to show the necessity and sufficiency of the convex hull description. Note that Equation (24c) together with (24a) and (24b) give

Downloaded from inforslink.org by [128.104.188.254] on 01 March 2016, at 11:56. For personal use only, all rights reserved.

redundant inequalities dominated by $0 \leq x_{ij} \leq 1$. Similarly, (24a) with (24d) and (24e) exactly give Equation (9d).

Next, we look at (24b) and (24e) together, which give

$$\begin{aligned} \sum_{(i,j) \in C} x_{ij} - (|C| - 1) &\leq \frac{1}{\Delta(S)} \sum_{(i,j) \in S} w_{ij}x_{ij} - \frac{1}{\Delta(S)} \sum_{(i,j) \in S} f_{ij} \\ \iff \Delta(S) \sum_{(i,j) \in C} x_{ij} - \Delta(S)(|C| - 1) &\leq \sum_{(i,j) \in S} w_{ij}x_{ij} - \sum_{(i,j) \in S} f_{ij} \\ \iff \sum_{(i,j) \in S} f_{ij} &\leq \Delta(S)(|C| - 1) + \sum_{(i,j) \in S} w_{ij}x_{ij} \\ &\quad - \Delta(S) \sum_{(i,j) \in S} x_{ij} - \Delta(S) \sum_{(i,j) \in C \setminus S} x_{ij} \\ \iff \sum_{(i,j) \in S} f_{ij} &\leq \Delta(S)(|C| - 1) \\ &\quad - \sum_{(i,j) \in S} [\Delta(S) - w_{ij}]x_{ij} - \Delta(S) \sum_{(i,j) \in C \setminus S} x_{ij}, \quad (25) \end{aligned}$$

for $S \subseteq C, \Delta(S) > 0$. Yet, this is the right inequality in (12). Finally, using a similar argument, if we look at (24b) and (24d) together, we get exactly the left inequality in (12) for $S \subseteq C, \Delta(S) > 0$, which concludes the proof. \square

Theorem 4.1 shows that the inequalities (12) are sufficient to define the convex hull of \mathcal{S}_C . In Theorem 4.2 we show that each inequality is also necessary by showing that they always define facets.

THEOREM 4.2. *The inequalities (12) are facet-defining for the set $\text{conv}(\mathcal{S}_C)$.*

PROOF. We prove the result only for the right inequality of (12), as a symmetric argument can be made for the left inequality. First, it is easy to establish that $\text{conv}(\mathcal{S}_C)$ is full-dimensional by producing $2|C| + 1$ affinely independent points that lie in (\mathcal{S}_C) . Let \mathcal{F} denote the face of $\text{conv}(\mathcal{S}_C)$ defined by

$$\mathcal{F} = \left\{ (f, x) \in \mathcal{S}_C : \sum_{(i,j) \in S} f_{ij} + \sum_{(i,j) \in S} [\Delta(S) - w_{ij}]x_{ij} + \Delta(S) \sum_{(i,j) \in C \setminus S} x_{ij} = \Delta(S)(|C| - 1) \right\}.$$

We produce $2|C|$ affinely independent points in \mathcal{F} for the case $|C \setminus S| \neq 1$ and $2|C| - 1$ linearly independent points in \mathcal{F} for the case $|C \setminus S| = 1$, which establishes the result.

Let $\hat{a} \in S$ define $\rho = w(C \setminus S)/w(S) \in [0, 1)$, let ϵ be a sufficiently small real number, and define the $|S|$ points $\chi^1(\hat{a})$ whose components take values

$$\begin{aligned} f_a &= \begin{cases} \rho w_a + \epsilon & \text{if } a \in S \setminus \hat{a} \\ \rho w_a - (|S| - 1)\epsilon & \text{if } a = \hat{a} \\ -w_a & \text{if } a \in C \setminus S \end{cases} \\ x_a &= 1 \quad \forall a \in C. \end{aligned}$$

Define an additional $|S|$ points $\chi^2(\hat{a})$ whose components take the values

$$\begin{aligned} f_a &= \begin{cases} w_a & \text{if } a \in C \setminus \hat{a} \\ 0 & \text{if } a = \hat{a} \end{cases} \\ x_a &= 1 \quad \forall a \in C \setminus \hat{a}, \\ x_{\hat{a}} &= 0. \end{aligned}$$

One can establish that both $\chi^1(\hat{a}), \chi^2(\hat{a}) \in \mathcal{F} \forall \hat{a} \in S$. If $S = C$, (i.e., $|C \setminus S| = 0$) these constitute $2|C|$ affinely independent points. Otherwise, the proof continues by defining $2|C \setminus S|$ points in \mathcal{F} .

For each $\tilde{a} \in C \setminus S$, define a point $\chi^3(\tilde{a})$ whose components take values

$$\begin{aligned} f_a &= \begin{cases} w_a & \text{if } a \in S \\ 0 & \text{if } a \in C \setminus S \end{cases} \\ x_a &= 1 \quad \forall a \in C \setminus \tilde{a}, \\ x_{\tilde{a}} &= 0. \end{aligned}$$

If $|C \setminus S| \geq 2$, we can define an additional point $\chi^4(\tilde{a}, \bar{a})$ for some $\bar{a} \in C \setminus S, \bar{a} \neq \tilde{a}$ whose components take values

$$\begin{aligned} f_a &= \begin{cases} w_a & \text{if } a \in S \cup \bar{a} \\ 0 & \text{if } a \in C \setminus S \setminus \bar{a} \end{cases} \\ x_a &= 1 \quad \forall a \in C \setminus \tilde{a}, \\ x_{\tilde{a}} &= 0. \end{aligned}$$

It can be shown that both $\chi^3(\tilde{a}), \chi^4(\tilde{a}, \bar{a}) \in \mathcal{F} \forall \tilde{a}, \bar{a} \in C \setminus S$. Then the set of points $\{\chi^1(\hat{a}), \chi^2(\hat{a}) : \hat{a} \in S\} \cup \{\chi^3(\tilde{a}), \chi^4(\tilde{a}, \bar{a}) : \text{each } a \in C \setminus S \text{ is chosen as } \tilde{a}, \bar{a} \text{ exactly once}\}$ is in \mathcal{F} and contains $2|C|$ points that are affinely independent.

In the case of $|C \setminus S| = 1$, we construct $2|C| - 1$ linearly independent points in \mathcal{F} . Consider the set of points $\{\chi^1(\hat{a}), \chi^2(\hat{a}) : \hat{a} \in S\} \cup \{\chi^3(\tilde{a}) : \tilde{a} \in C \setminus S\} \subseteq \mathcal{F}$ and let $p^1, p^2, \dots, p^{2|C|-1} \in \mathbb{R}^{2|C|}$ denote its $2|C| - 1$ elements. We prove their linear independence by showing that $\sum_{i=1}^{2|C|-1} \lambda_i p^i = \mathbf{0}, \lambda \in \mathbb{R}^{2|C|-1}$ implies $\lambda_i = 0 \forall i = 1, 2, \dots, 2|C| - 1$. For simplicity of notation, we use numerical index for edges contained in cycle. Let $C = \{1, 2, \dots, n\}$ and $S = \{1, 2, \dots, n - 1\}$. Then $\sum_{i=1}^{2|C|-1} \lambda_i p^i = \mathbf{0}$ can be equivalently written as the following system of equations:

$$\sum_{i=1}^{n-1} (\rho w_k + \epsilon) \lambda_i - (n - 1)\epsilon \lambda_k + \sum_{i=n}^{2n-1} \lambda_i w_k - \lambda_{n+k} w_k = 0 \quad \forall k = 1, 2, \dots, n - 1, \quad (26)$$

$$\sum_{i=1}^{2n-1} \lambda_i - \lambda_k = 0 \quad \forall k = n, n + 1, \dots, 2n - 1. \quad (27)$$

From the n inequalities in (27), we obtain $\lambda_n = \lambda_{n+1} = \dots = \lambda_{2n-1} = \sum_{i=1}^{2n-1} \lambda_i = \bar{\lambda}$ for some number $\bar{\lambda}$ which implies

$\sum_{i=1}^{n-1} \lambda_i = (1-n)\bar{\lambda}$. Plugging the former equations into (26) results in

$$\lambda_k = (((1-\rho)w_k - \epsilon)/\epsilon)\bar{\lambda} \quad \forall k = 1, 2, \dots, n-1.$$

Aggregating these $n-1$ inequalities, we obtain

$$\begin{aligned} \sum_{k=1}^{n-1} \lambda_k &= \sum_{k=1}^{n-1} ((1-\rho)/\epsilon)w_k\bar{\lambda} - \sum_{k=1}^{n-1} \bar{\lambda} = (1-n)\bar{\lambda} \\ \Leftrightarrow & ((1-w(C \setminus S)/w(S))w(S)/\epsilon = 0 \\ \Leftrightarrow & ((2w(S) - w(C))/\epsilon)\bar{\lambda} = 0 \\ \Leftrightarrow & \bar{\lambda} = 0 \\ \Rightarrow & \lambda_i = 0 \quad \forall i = 1, 2, \dots, 2|C| - 1. \quad \square \end{aligned}$$

4.2. Separation

We now investigate the separation problem over constraints (12). Given a fractional point (\hat{f}, \hat{x}) , we first define $K_C = 1 - \sum_{(i,j) \in C} (1 - \hat{x}_{ij})$. We focus on the right inequality in (12); the left is similarly analyzed. For the given cycle C and $S \subseteq C$ with $\Delta(S) > 0$ the inequality takes the form:

$$\sum_{(i,j) \in S} f_{ij} + \sum_{(i,j) \in S} [-w_{ij}]x_{ij} + \Delta(S) \sum_{(i,j) \in C} x_{ij} \leq \Delta(S)(|C| - 1).$$

For convenience, we rearrange the inequality as follows:

$$\sum_{(i,j) \in S} (f_{ij} - w_{ij}x_{ij}) + \Delta(S) \left(1 - \sum_{(i,j) \in C} (1 - x_{ij}) \right) \leq 0. \quad (28)$$

Our aim is to determine if there exists $S \subseteq C$ with $\Delta(S) > 0$ such that the inequality (28) is violated, that is, the right-hand side of (28), defined as $\text{viol}(S)$, is strictly greater than 0, as shown below:

$$\text{viol}(S) := \sum_{(i,j) \in S} (\hat{f}_{ij} - w_{ij}\hat{x}_{ij}) + \Delta(S)K_C > 0. \quad (29)$$

Recalling that $\Delta(S) = w(S) - w(C \setminus S) = 2w(S) - w(C)$, this can be determined by solving

$$\max_{S \subseteq C} \left\{ \sum_{(i,j) \in S} (\hat{f}_{ij} - w_{ij}\hat{x}_{ij}) + \Delta(S)K_C : \Delta(S) > 0 \right\}. \quad (30)$$

A violated inequality exists if and only if the optimal value of (30) is positive. Introducing binary variables z_{ij} for $(i, j) \in C$ to indicate whether line $(i, j) \in S$, (30) can be reformulated as follows:

$$\begin{aligned} \max_{z \in \{0,1\}^{|C|}} & \left\{ \sum_{(i,j) \in C} (\hat{f}_{ij} - w_{ij}\hat{x}_{ij})z_{ij} + \sum_{(i,j) \in C} w_{ij}K_C z_{ij} \right. \\ & \left. - \sum_{(i,j) \in C} w_{ij}K_C(1 - z_{ij}) : \right. \\ & \left. \sum_{(i,j) \in C} w_{ij}z_{ij} - \sum_{(i,j) \in C} w_{ij}(1 - z_{ij}) > 0 \right\} \\ & = -w(C)K_C + \max_{z \in \{0,1\}^{|C|}} \left\{ \sum_{(i,j) \in C} (\hat{f}_{ij} - w_{ij}\hat{x}_{ij} + 2w_{ij}K_C)z_{ij} : \right. \\ & \left. \sum_{(i,j) \in C} w_{ij}z_{ij} > \frac{1}{2}w(C) \right\}. \quad (31) \end{aligned}$$

Note that here we need the condition that $\Delta(S) > 0$, which yields a knapsack problem. A similar minimization problem can be posed to separate left inequalities.

There is a necessary condition for a cycle C to have a violating inequality of form (12) given in Proposition 4.3.

PROPOSITION 4.3. *Given (\hat{f}, \hat{x}) for a cycle C , if $K_C = 1 - \sum_{(i,j) \in C} (1 - \hat{x}_{ij}) \leq 0$, then inequalities (12) are not violated.*

PROOF. Consider right inequalities first. If $K_C < 0$, then given an optimal solution z to problem (31), we have $\sum_{(i,j) \in C} (\hat{f}_{ij} - w_{ij}\hat{x}_{ij} + 2w_{ij}K_C)z_{ij} < w(C)K_C$ since $\sum_{(i,j) \in C} w_{ij}z_{ij} > \frac{1}{2}w(C)$ and $f_{ij} \leq w_{ij}x_{ij}$. Therefore, no violating inequality exists. If $K_C = 0$, then given an optimal solution z to problem (31), we have $\sum_{(i,j) \in C} (\hat{f}_{ij} - w_{ij}\hat{x}_{ij} + 2w_{ij}K_C)z_{ij} \leq 0 = w(C)K_C$ since $\hat{f}_{ij} \leq w_{ij}\hat{x}_{ij}$. Therefore, no violating inequality exists. A similar argument can be used to show that the requirement $K_C > 0$ is necessary for a left inequality to be violating. \square

Although (31) formulates the separation problem of inequalities (12) as a knapsack problem, the special structure of this knapsack problem enables it to be solved efficiently. In fact, we could solve a linear program derived from the extended formulation (17) to solve the separation problem over $\text{conv}(\mathcal{S}_C)$. However, we next show how separation of the cycle inequalities can be efficiently accomplished in closed form. Define

$$S_C^* = \{(i, j) \in C : \hat{f}_{ij} - w_{ij}\hat{x}_{ij} + 2w_{ij}K_C > 0\}.$$

The following proposition shows that S_C^* is the only subset that needs to be considered when solving the separation problem for cycle C .

PROPOSITION 4.4. *Assume that $K_C > 0$. If there is any $S \subseteq C$ with $\Delta(S) > 0$ and $\text{viol}(S) > 0$, then the separation problem (30) is solved by S_C^* .*

PROOF. First, suppose that $\Delta(S_C^*) > 0$, so that S_C^* is a feasible solution to (30). Then, since, by construction, it contains every element in C that has a positive contribution to the objective $\text{viol}(S)$, this is an optimal solution to (30). Now, suppose that $\Delta(S_C^*) \leq 0$, i.e., $2w(S_C^*) - w(C) \leq 0$. Then,

$$\text{viol}(S_C^*) = \sum_{(i,j) \in S_C^*} (\hat{f}_{ij} - w_{ij}\hat{x}_{ij}) + (2w(S_C^*) - w(C))K_C \leq 0$$

because the first term is nonpositive due to $\hat{f}_{ij} \leq w_{ij}\hat{x}_{ij}$; the second term is nonpositive by assumption. Now, because each element $(i, j) \in S_C^*$ contributes a positive amount to the objective in (30) and a positive amount to the constraint, there must exist an optimal solution of (30) that contains S_C^* as a subset. Yet any set T that contains S_C^* as a subset has $\text{viol}(T) \leq \text{viol}(S_C^*) \leq 0$, since elements $(i, j) \notin S_C^*$ contribute a nonpositive amount to the objective. Thus, in the case $\Delta(S_C^*) < 0$, there is no $S \subseteq C$ with $\Delta(S) > 0$ and $\text{viol}(S) > 0$. \square

Recall from Proposition 4.3 that $K_C > 0$ is a necessary condition for a violated inequality to exist from cycle C .

Thus, for a given cycle C with $K_C > 0$, a violated inequality exists for this cycle if and only if:

$$\sum_{(i,j) \in C} \left((\hat{f}_{ij} - w_{ij}\hat{x}_{ij} + 2w_{ij}K_C)_+ - w_{ij}K_C \right) > 0, \quad (32)$$

where $(\cdot)_+ = \max\{\cdot, 0\}$. The separation problem then reduces to a search for a cycle C having $K_C > 0$ and which satisfies (32).

5. Algorithms

In this section, we describe our algorithmic framework for solving the DC switching problem, beginning with §5.1 where we describe the overall algorithm. Section 5.2 describes the algorithms we implemented for separating over cycle inequalities (12) for a fixed cycle C . §5.3 describes our procedure for generating a set of cycles over which we will perform the separation.

5.1. Overall Algorithm

The overall structure of the proposed algorithm is shown in Algorithm 1. The preprocessing phase of the algorithm aims to add cycle inequalities to strengthen the linear programming (LP) relaxation of the Angle Formulation (9). First, we generate a set of cycles over the original power network, and solve the LP relaxation of (9). Then, a separation algorithm finds all the cycle inequalities (12) that are violated by the LP solution over the generated set of cycles. These violated inequalities are added to the LP relaxation as cuts. This procedure is iterated a number of times to strengthen the LP relaxation, which is then fed to the MIP solver (we use CPLEX). We prefer to implement our separation in this “cut-and-branch” manner to investigate the utility of the cutting planes when combined with all advanced features of modern MIP software. An alternative approach would be to use the User Cut callback facility of CPLEX. However, this procedure disables many advanced features of the solver such as dynamic search. We implemented a version of our cutting planes using the CPLEX callback features and found that, on average, the performance was around 30% worse than with our cut-and-branch Algorithm 1.

Algorithm 1 (Overall algorithm for DC switching)

1. Preprocessing:
 - (a) Generate a set Γ of cycles.
 - (b) Strengthen LP relaxation of Angle Formulation (9) by adding violated cycle inequalities (12) from each cycle $C \in \Gamma$ (Separation Algorithms 2 or 3).
2. Solve the Angle Formulation with added cuts, using CPLEX.

5.2. Separation Algorithms

For a given LP relaxation solution, the separation algorithm implements the ideas presented in §4.2 to identify all violated cycle constraints of the form (12) for a predetermined set of cycles. The procedure is summarized in Algorithm 2.

Algorithm 2 (Separation algorithm)

Given a set Γ of cycles and a LP relaxation solution (\hat{f}, \hat{x}) .

for every cycle $C \in \Gamma$ **do**

Compute $K_C = 1 - \sum_{a \in C} (1 - \hat{x}_a)$.

if $K_C > 0$ **then**

for each $a \in C$,

compute $z_a = \begin{cases} 1 & \text{if } \hat{f}_a - w_a\hat{x}_a + 2w_aK_C \geq 0 \\ 0 & \text{otherwise} \end{cases}$.

if $\sum_{a \in C} w_a z_a > \frac{1}{2}w(C)$ **and**

$\sum_{a \in C} ((\hat{f}_a - w_a\hat{x}_a + 2w_aK_C)_+ - w_aK_C) > 0$ **then**
A violated cycle inequality for C is found.

end if

end if

end for

Algorithm 2 generates a *single* violating inequality for each cycle, if such a violated inequality exists. However, the method can be extended to find all violating inequalities for a cycle. This procedure is summarized in Algorithm 3, which uses a recursive subroutine described in Algorithm 4.

Algorithm 3 (Finding all valid inequalities)

Given a cycle C , define $v_{ij} = \hat{f}_a - w_a\hat{x}_a + 2w_aK_C$ for $a \in C$. Set $S = \{a \in C : v_a \geq 0\}$ and denote $C \setminus S = \{a_1, \dots, a_n\}$. Calculate $v(S) = \sum_{a \in S} v_a$ and $w(S) = \sum_{a \in S} w_a$. Recursion($S, 0$).

Algorithm 4 (Recursion(S, k))

if $v(S) \leq w(C)K_C$ or $k = n$ **then**

Stop.

end if

if $v(S) > w(C)K_C$ and $w(S) > \frac{1}{2}w(C)$ **then**

A violating inequality is found.

end if

for $l = k + 1, \dots, n$ **do**

Recursion($S \cup \{a_l\}, l$)

end for

5.3. Cycle Basis Algorithm

This section describes how to generate a set of cycles for the preprocessing phase of Algorithm 1. The number of cycles in a graph $G = (V, E)$ grows exponentially in $|V|$. Thus, in computations, finding all cycles is not efficient. Instead, we find a cycle basis for the original power network and use the cycle basis to generate cycles for separation. There are many algorithms for finding a cycle basis Kavitha et al. (2009). We use a simple algorithm based on the lower/upper (LU) decomposition of the incidence matrix of the graph G .

This choice of algorithm was arbitrary. We have no reason to believe that this specific choice of algorithm to create a cycle basis has a significant impact on performance of the cutting planes.

Given an initial set of cycles Γ coming from the cycle basis, the following procedure is used to generate additional cycles from which we may apply the separation procedures 2 and 3. Any pair of cycles in $\Gamma := \mathcal{C}^0$ that share at least one common edge can be combined to form a new cycle by removing the common edges. Denote $\bar{\mathcal{C}}^0$ as the set of all the new cycles thus generated from \mathcal{C}^0 . Then, the set $\mathcal{C}^1 := \mathcal{C}^0 \cup \bar{\mathcal{C}}^0$ has more cycles than the cycle basis \mathcal{C}_b . This process can be repeated to generate sets $\mathcal{C}^{k+1} := \mathcal{C}^k \cup \bar{\mathcal{C}}^k$ for $k \geq 1$.

Given a set of cycles Γ , we can use Algorithms 2 or 3 to identify and add all violated cycle inequalities for that set of cycles to the LP relaxation of the Angle Formulation. We solve this strengthened LP relaxation again and add further violated cycle inequalities. This procedure can be carried out in several iterations (five times for our experiments) to produce a strengthened LP relaxation which is eventually passed to the MIP solver.

6. Computational Results

In this section, we present extensive computational studies that demonstrate the effectiveness of our proposed cut-and-branch algorithms on the DC-OTS problem. Section 6.1 explains how the test instances are generated. Section 6.2 compares the default branch-and-cut algorithm of CPLEX with two algorithms that use the cycle inequalities (12). The first algorithm generates inequalities from cycles in one fixed cycle basis; the other generates inequalities from a larger set of cycles. The results show that the proposed algorithm with cutting planes separated from more cycles consistently outperforms the default algorithm in terms of the size of the branch-and-bound tree, the total computation time, and the number of instances solved within the time limit.

For all experiments, we use a single thread in a 64-bit computer with Intel Core i5 CPU 3.33 GHz processor and 4 GB RAM. Codes are written in the C# language. Given that the transmission switching problem is usually solved under a limited time budget, the relative optimality gap is set to a moderate amount of 0.1% for all MIPs solved using CPLEX 12.4 (CPLEX 2011). We set a time limit of one hour in all experiments.

6.1. Instance Generation

Our computational experiments focus on instances where the solution of the DC-OTS is significantly different than the solution of the DC-OPF. In addition to selecting instances where switching made an appreciable instance, we selected instances whose network size was large enough so that the instances were not trivial for existing algorithms, but small enough to not be intractable. The 118-bus instance case118B generated in Blumsack (2006) turns out to be

suitable for our purposes. We we also modified the 300-bus instance case300 so that transmission switching produces meaningfully different solutions from the OPF problem without switching. Furthermore, to extensively test the effectiveness of the proposed cuts and separation algorithms, we generate the following five sets of instances based on case118B and case300:

- Set 118_15: We generate 35 instances by modifying case118B, where the load at each bus of the original case118B is increased by a discrete random variable following a uniform distribution on $[0, 15]$.
 - Set 118_15_6: To each of the instances in Set 118_15, we randomly add five new lines to the power network, each creating a 6-cycle. The transmission limits for the lines in the cycle are set to 30% of the smallest capacity \bar{f}_{ij} in the network. B_{ij} is chosen randomly from one of the lines that is already in the original network.
 - Set 118_15_16: The instances are constructed the same as in Set 118_15_6, except that a 16-cycle is created by adding five new transmission lines.
 - Set 118_9G: We generate 35 different instances from case118B, where the original load at each bus is increased by a discrete random variable following a uniform distribution on $[0, 9]$. Furthermore, the generation topology of the network is changed. In particular, a generator at bus i is moved to one of its neighboring buses or stays at its current location with equal probability.
 - Set 300_5: We generate 35 different instances from case300, where the original load at each node is incremented by a discrete random variable following a uniform distribution on $[-5, 5]$. Also, eight generators are turned off and the cost coefficients of remaining generators are updated to be similar to the objective coefficients in Blumsack (2006). Finally, more restrictive transmission line limits are imposed.
- These instances can be downloaded from <https://sites.google.com/site/burakkocuk/research>.

6.2. DC Transmission Switching

We now investigate the computational impact of using the proposed valid inequalities within the proposed cut-and-branch procedure. We compare the following three solution procedures:

1. The angle formulation (9) solved with CPLEX, abbreviated by Default;
2. The angle formulation (9) with valid inequalities (12) found using cycles coming from a single cycle basis, abbreviated by BasicCycles;
3. The angle formulation (9) with valid inequalities (12) coming from more cycles than a cycle basis, abbreviated by MoreCycles. The procedure for generating additional cycles for separation is discussed in §5.3. We use the set of cycles \mathcal{C}^2 for the 118-bus networks, where $|\mathcal{C}^2| \approx 3,500$. For the 300-bus networks, \mathcal{C}^2 has more than 37,000 cycles, which makes the separation procedure computationally expensive. For the 300-bus networks, we randomly select 10% of the cycles in \mathcal{C}^2 for separation.

We conducted preliminary experiments comparing Algorithms 2 and 3 when using the valid inequalities (12), and found that Algorithm 3 yielded consistently better performance. Therefore, we use Algorithm 3 as the separation algorithm for inequalities (12) in both BasicCycles and MoreCycles.

Tables 1(a)–1(e) show the computational results for the five sets of test instances described in §6.1. To measure the impact of the cuts on closing the integrality gap, we use the following objective values:

- z_{LP} : The objective value of the LP relaxation at the root node without inequalities (12) and without CPLEX cuts;
- z_{LP}^{cuts} : The objective value of the LP relaxation at the root node with inequalities (12) and without CPLEX cuts;
- z_{LP}^{root} : The objective value of the LP relaxation at the root node with inequalities (12) and with CPLEX cuts;
- z_{IP} : The objective value of the final integer solution of the switching problem.

The integrality gap measures reported in the tables are defined as

- “Initial LP Gap (%)” := $100\% \times (z_{IP} - z_{LP})/z_{IP}$;
- “Gap Closed by Cuts (%)” := $100\% \times (z_{LP}^{cuts} - z_{LP})/(z_{IP} - z_{LP})$;
- “Root Gap Closed (%)” := $100\% \times (z_{LP}^{root} - z_{LP})/(z_{IP} - z_{LP})$.

Other performance metrics reported in Tables 1(a)–1(e) are the average number of valid inequalities generated by the proposed algorithm (row “# Cuts”); the average preprocessing time for generating valid inequalities (“Preprocessing Time”), which includes the time for solving five rounds of the LP relaxation of the switching problem and the associated separation problems; the average total computation time including the preprocessing time (“Total Time”); the number of Branch-and-Bound nodes (“B&B Nodes”); the number of unsolved instances within a time limit of one hour (“# Unsolved”); and the average final optimality gap for unsolved instances (“Unsolved Opt Gap (%)”). For each metric, we report the arithmetic mean (the first number) and the geometric mean (the second number).

From these tables, we can see that the proposed algorithm MoreCycles consistently outperforms the default algorithm in terms of the percentage of optimality gap closed at the root node, the size of the Branch-and-Bound tree, the total computation time, and the number of instances solved.

Figures 1(a)–1(e) show the performance profiles of the three algorithms on the five sets of test instances. In particular, each curve in a performance profile is the cumulative distribution function for the ratio of one algorithm’s runtime to the best runtime among the three (Dolan and Moré 2002). Set 118_15 is a relatively easy test set. Figure 1(a) shows that, for 42.9% of the instances, the Default algorithm is the fastest algorithm, the BasicCycles algorithm is fastest on 37.1%, and the MoreCycles algorithm is fastest on 20%.

However, if we choose to be within a factor of two of the fastest algorithm as the comparison criterion, both BasicCycles and MoreCycles surpass Default. BasicCycles solves all the instances and is the dominating performance for this set of instances.

Figure 1(b) shows the results for Set 118_9G. BasicCycles is the fastest algorithm in 40% of the instances; MoreCycles and Default have a success rate of 20% of being the fastest. If we choose to be within a factor of four of the fastest algorithm as the interest of comparison, then MoreCycles starts to outperform BasicCycles. Also, MoreCycles solves 74.3% of the instances, which is the highest among the three.

For instance sets 118_15_6 and 118_15_16, Figures 1(c)–1(d) show that BasicCycles is the fastest algorithm in the highest percentage of instances. For the ratio factor higher than one, BasicCycles and MoreCycles clearly dominate Default, and both solve significantly more instances than Default. MoreCycles is the most robust algorithm in the sense that it solves the most instances.

On the 300_5 instance set, Figure 1(e) shows that MoreCycles is the fastest in the largest fraction of instances and that it also solves the most instances. BasicCycles is dominated by the other two methods for this set of instances.

Figure 1(f) shows the performance profiles of the three algorithms over all the five test sets. BasicCycles is the fastest algorithm in 38.3% of the instances, whereas Default is the fastest in 29.7% of the instances, and MoreCycles is the fastest in 25.7% of the instances. If we look at the algorithm that can solve 75% of all the instances with the highest efficiency, then BasicCycles and MoreCycles have almost identical performance, and both significantly dominate Default. MoreCycles solves slightly more instances than BasicCycles within the time limit. In summary, the performance profiles show that BasicCycles has the highest probability of being the fastest algorithm and MoreCycles solves the most instances. These experiments demonstrate that the cycle inequalities (12) can be quite useful in improving the performance of state-of-the-art MIP software for solving the DC-OTS.

6.3. Sensitivity Analysis

Previous literature on the DC-OTS demonstrates that significant cost savings can be achieved by switching off only a few lines (Fisher et al. 2008, Wu and Cheung 2013). However, the optimal solutions obtained by the integer program turn off a significantly larger number of lines than suggested by previous studies. Specifically, the average number of lines turned off in the optimal solutions to the 118-bus instances is 42; the maximum number turned off is 57. For the 300-bus instances, an average of 85 lines are turned off in the optimal solutions, with a maximum of 107. This surprising result is a consequence of our observation that there are *many* optimal or near-optimal topologies for the DC-OTS. To demonstrate

Note. For each metric, we report the arithmetic and geometric mean, respectively.

the impact of switching off fewer lines than suggested by the optimal solution to the integer program, we performed a sensitivity analysis of the cost versus the number of lines N that are allowed to be switched off.

In this analysis, we chose one instance from each of the five sets whose optimal solution had a large number of lines switched off (41, 38, 41, 48, and 91, respectively this is henceforth referred to as instances (a), (b), (c), (d), and

Figure 1. Performance profiles for test instances.

(e) and solved a number of DC-OTS instances with the cardinality constraint:

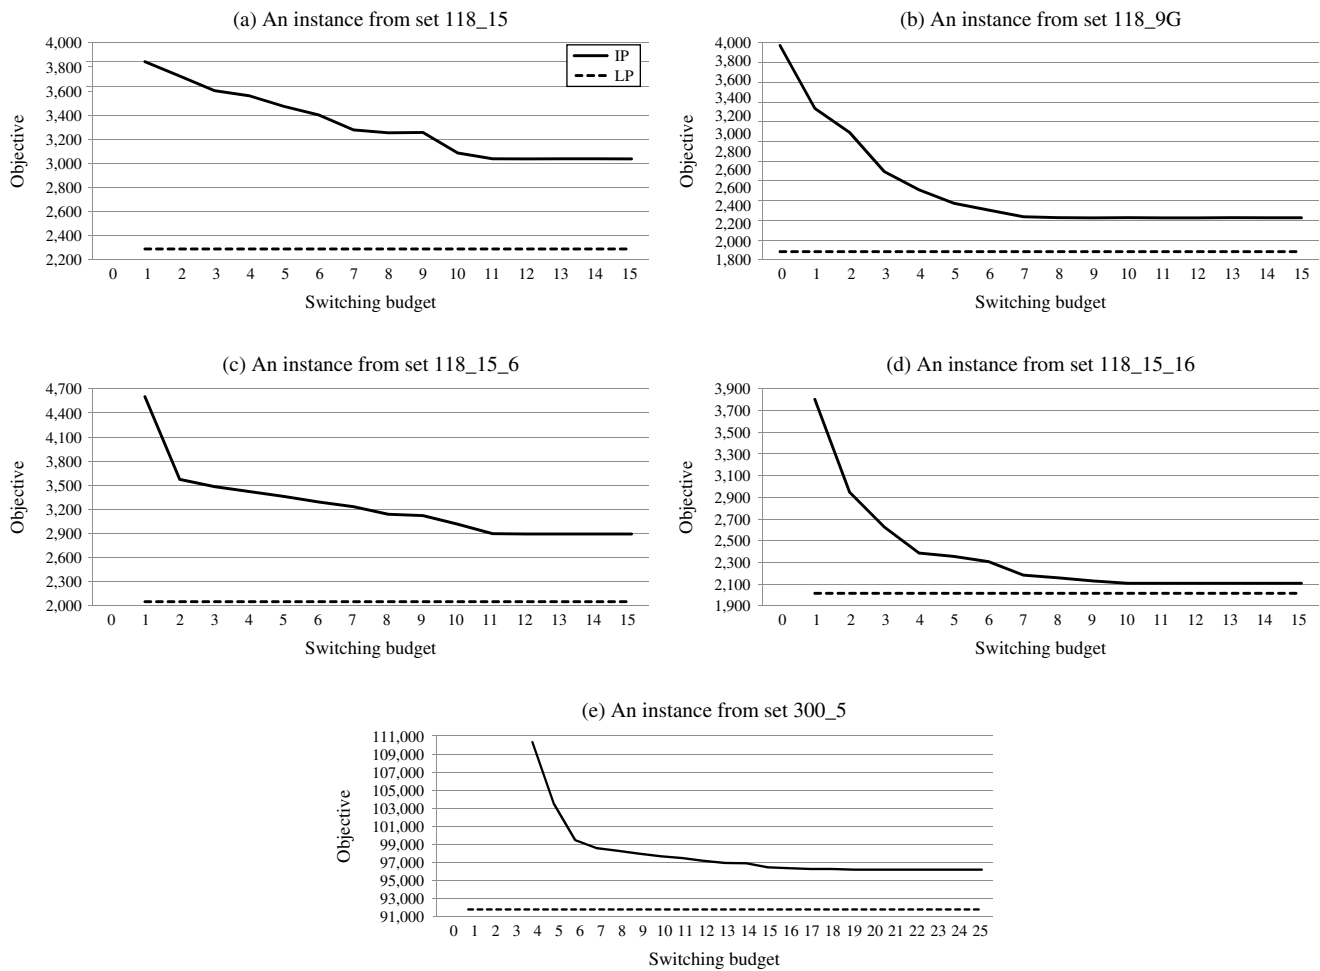

$$\sum_{(i, j) \in \mathcal{L}} x_{ij} \geq |\mathcal{L}| - N \tag{33}$$

added to the formulation. Here, N is the *switching budget*, that is, the number of lines allowed to be switched off (note

that $N = 0$ corresponds to DC-OPF). We experimented with different N values. The results are given in Figures 2(a)–2(e). We make the following observations:

- DC-OPF versions of instances (a), (c), (d), and (e) are infeasible.
- Once a particular instance becomes feasible, increasing the switching budget has a significant impact on the objective

Figure 2. Evolution of objective function (IP) and linear programming relaxation (LP) with respect to different switching budgets for five instances.

value for the first few lines (especially, for instances (b), (d), and (e)).

- Nevertheless, the full cost benefit can only be realized by switching off several lines.
- Switching off 11 lines is enough for 118-bus instances (a), (b), (c), and (d) to achieve the maximum cost benefit (just seven lines are needed for instance (b)).
- For the 300-bus instance, switching off 15 lines yields nearly the maximum cost benefit.
- The LP relaxation value is not affected by the switching budget.

Our results support the observation that most, although not all, of the cost benefits in transmission switching can be realized by switching off only a few lines. This has a positive impact on the robustness of the network. In our experience, the MIP instances with cardinality constraints were more time consuming to solve than without the cardinality constraint. For example, the two instances that had the largest number of switched off lines in the optimal solutions we found (i.e., the 118-bus instance with 57 lines switched off and the 300-bus instance with 107 lines switched off) could not be solved in one hour for most switching budgets. Our observation

that the LP relaxation value is not affected by the switching budget may help explain this. Since the optimal IP value is larger for smaller switching budgets, the LP relaxation gap is larger for these instances.

7. Conclusions

In this paper, we propose new cycle-based formulations for the optimal power flow problem and the optimal transmission switching problems that use the DC approximation to the power flow equations. We characterize the convex hull of a cycle-induced substructure in the new formulation, which provides strong valid inequalities that we may add to improve the new formulation. We demonstrate that separating the new inequalities may be done in linear time for a fixed cycle. We conduct extensive experiments to show that the valid inequalities are very useful in reducing the size of the search tree and the computation time for the DC-OTS problem.

The inequalities we derive may be gainfully used for *any* power systems problem that involves the addition or removal of transmission lines and for which the DC approximation to power flow is sufficient for engineering purposes. We

will pursue the application of these inequalities to other important power systems planning and operations problems as a future line of research. Other future lines of research include investigation of more complicated substructures of the new formulation, and engineering the cutting plane procedure to effectively solve larger scale networks. As an example of studying more complicated substructures, one reviewer observed that the substructure we study does not involve flow balance constraints. Stronger relaxations could be obtained by separating cutting planes using an extended formulation similar to (14) that includes flow balance constraints.

Acknowledgments

The authors thank the reviewers for their constructive comments and in particular for suggesting the experiments in §6.3. These have significantly improved the paper. The work of the second author, the fourth author, and the fifth author was supported in part by the U.S. Department of Energy, Office of Science, Office of Advanced Scientific Computing Research, Applied Mathematics program under contract number DE-AC02-06CH11357. The third author acknowledges the support provided by the National Science Foundation [Grant CCF-1415460]. The sixth author acknowledges the support provided by National Science Foundation [Grant CCF-1331426].

Burak Kocuk received M.S. degree in industrial engineering Bogazici University, Istanbul. Currently, he is pursuing a doctorate in operations research in the H. Milton Stewart School of Industrial and Systems Engineering at the Georgia Institute of Technology. His doctoral studies focus on optimization problems in power systems, in particular, optimal power flow and transmission switching.

Hyemin Jeon is a postdoctoral scholar in the Department of Industrial Engineering and Operations Research at the University of California, Berkeley. Jeon received her doctorate from the University of Wisconsin-Madison in 2015. Her primary research area is computational optimization with a focus on mixed-integer programming and conic programming.

Santanu S. Dey is an associate professor in the H. Milton Stewart School of Industrial and Systems Engineering at the Georgia Institute of Technology. His primary research interest is non-convex optimization, specifically mixed-integer linear programming, mixed integer nonlinear programming, and global optimization. His honors include the INFORMS George Nicholson Student Paper Competition, IBM Faculty award, and the National Science Foundation CAREER award.

Jeff Linderoth is a professor in the Department of Industrial and Systems Engineering and the Department of Computer Sciences (by courtesy) at the University of Wisconsin-Madison. He is also a Fellow at the Wisconsin Institutes of Discovery. His primary research interest is computational methods for solving integer and stochastic programs. Previous awards include the DOE Early Career Award, the SIAM Activity Group on Optimization Prize, and the INFORMS Computing Society ICS Prize.

Jim Luedtke is an associate professor in the Department of Industrial and Systems Engineering at the University of Wisconsin-Madison. Luedtke's research focus is methods for solving stochastic and mixed-integer optimization problems and applications of such

models. His honors include the NSF CAREER award and the INFORMS Optimization Society Prize for Young Researchers. He was also a finalist in the INFORMS JFIG Best Paper competition.

Xu Andy Sun is currently an assistant professor in the H. Milton Stewart School of Industrial and Systems Engineering at the Georgia Institute of Technology. His primary research focus is

developing novel optimization models and rigorous methodologies to solve challenging problems in electric energy systems. Previous awards include INFORMS Georgia B. Dantzig Dissertation Award (third place), the INFORMS JFIG Best Paper Competition (third place), and the INFORMS Energy Best Paper Competition (second place).
